Low birth weight (LBW) is defined as a birth weight of less than 2500 g (5.5 lb) and is a risk factor for poor health outcomes in children and adults. LBW is often the result of poor nutrition and health during pregnancy. The purpose of this study was to determine the prevalence of LBW in a population of low-income, urban, African American women and to identify factors associated with LBW. A cross-sectional study was conducted in a community health center in an inner-city area of Chicago. Data were collected from 1998 to 2000. The study included 1,000 women who had given birth in the past 12 months. The prevalence of LBW was 11.5%. Factors associated with LBW included low maternal education, low maternal income, and low maternal weight gain during pregnancy. The results of this study suggest that interventions to improve maternal health and nutrition during pregnancy may reduce the prevalence of LBW.
